

MIT Transit Service Reliability

- Impacts of unreliability
- Causes of unreliability
- Reliability Metrics
- Real-Time Control Strategies

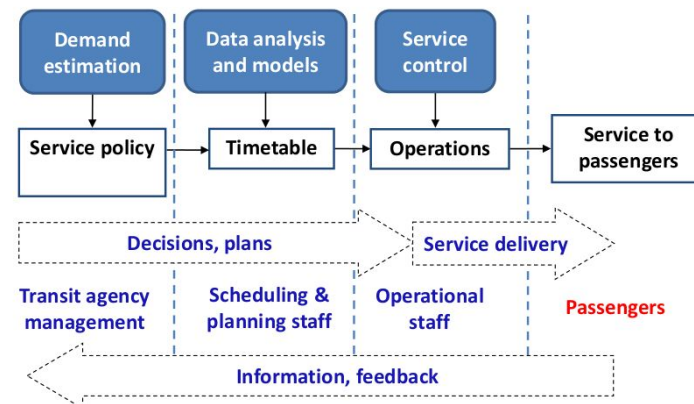

MIT Impacts of Unreliability

- Passenger impacts
 - Longer wait times
 - Need for trip time reliability buffer
 - Higher loads (uncomfortable and slow rides)
- Agency impacts
 - Increased costs
 - Reduced ridership and revenue
 - Reduced operator morale
 - Public and political problem
 - Reduced effective capacity

MIT Causes of Unreliability

- External
 - Traffic and traffic signals
 - Demand
 - Incidents (e.g. medical emergency)
- Internal
 - Equipment failure
 - Insufficient resources
 - Poor operations planning
 - Lack of supervision and control
 - Human driver behavior

Data-Driven Reliability Management

- Automated Data Collection Systems (AVL, AFC, APC) make it easier to measure reliability
- Automated scheduling systems make it easier to revise schedules
- Improved communications makes it easier to adjust operations plans in real time

Reliability as a Performance Measure

- Reliability is not the only service dimension of value
 - Speed/trip time
 - Productivity
 - Reliability means different things
 - To different customers
 - On different services
 - A single measure of effectiveness focused on reliability may lead to poor decisions
- ... but ...
- We do need to measure performance with respect to reliability

Reliability on Low Frequency Service

Most customers time their arrival at stops/stations based on expected service departure times (e.g. schedule)

- On-time performance is critical, for example:
 - 1 minute early to 5 minutes late
 - 0 minutes early to 3 minutes late
 - 0 minutes early to 1 minutes late
- Little interaction between successive vehicles
- Real-time information is changing this
 - Poorly understood
 - In what manner?
 - To what extent?
 - What are the implications?

Reliability on High Frequency Service

- Most customers do not time their arrival at stops with service departures
 - Expected wait time depends on mean and variance of headways
 - Punctuality is not so critical
 - Extensive interaction between successive vehicles:
 - Vehicle bunching
 - Long gaps
- ... but ...
- High frequency routes can have branches and short route variants, so many customers may still behave like those on low frequency routes
 - Schedule control is much easier than headway control

MIT Reliability Buffer Time

High Frequency Service, Closed Fare System

- use tap-in and tap-out times to measure actual station-station journey times
- characterize journey time distributions measures such as Reliability Buffer Time (at O-D level)

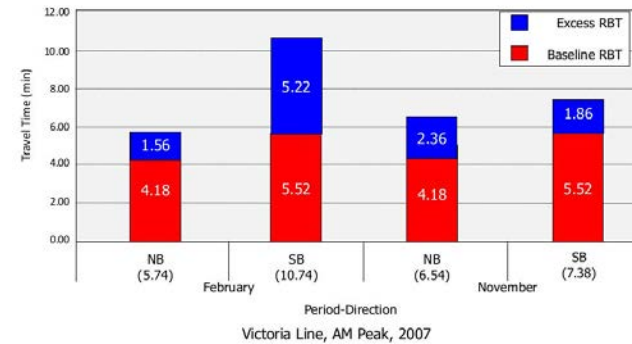

RBT = 95th percentile travel time – median travel time
 additional time a passenger must budget to arrive late no more than 5% of the time

 Lecture 20, Spring 2017

11

MIT Reliability Metrics - Bus

In contracted service delivery context, need to distinguish between:

1. Contractor performance: measure against contracted service expectations
2. Performance as seen by passenger

If service is unreliable, *the passenger* doesn't care whether the problem was caused by traffic or poor operator behavior, but *the authority* must be sure which caused the problem.

1.258J 11.541J ESD.226J
 Lecture 20, Spring 2017

12

Reliability Metrics - Bus

Challenge to measure passenger journey time because

- (typically) no tap-off, just tap-on
- tap-on occurs after wait at stop, but wait is an important part of journey time

Strategy to use

- Infer destinations using trip-chaining (ODX)
- Use AVL to estimate
 - average passenger wait time
 - based on assumed passenger arrival process
 - actual in-vehicle time

Reliability Management Strategies

Preventive

- Maintain normal service; robust operating plans
- Reduce probability of problems occurring

Corrective

- Return to normal service once problems arise
- Minimize impact on passengers

Preventive Strategies

- Reserve fleet of drivers and vehicles
- Exclusive bus lanes
- Traffic signal priority
- Route design strategies: shorter routes, less stops
- Schedule planning
- Supervision

Impact of Schedules

Critical decisions

- Cycle time/half cycle time: impacts cost and terminal departure reliability
 - Allocation of time between running and recovery time
- Time Points: impacts cycle time and/or recovery time, reliability along route and passenger trip time
 - Number and location
 - Schedule at each time point

MIT Impact of Schedules

Traditional scheduling approach

- Set half cycle time so that 90-95% of vehicle departures are on time
- Set time point scheduled times at 65 percentile of observed running times

... but ...

- This doesn't recognize the feedback between scheduled time and operating speed
- It is not sensitive to the ratio of passengers on board versus passengers waiting at time point and further down route

1.258J 11.541J ESD.226J
Lecture 20, Spring 2017

17

MIT Corrective Strategies

- Supervision, operations control
 - Holding: schedule-based vs. headway-based
 - Transit Signal Priority
 - Deadheading
 - Expressing
 - Short-turning
 - Use of reserve vehicles
- } major disruption strategies for high-frequency service

1.258J 11.541J ESD.226J
Lecture 20, Spring 2017

18

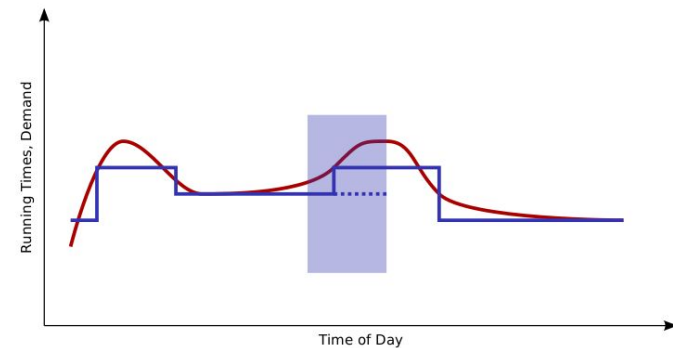

MIT Holding Strategies

- Schedule adherence
- Scheduled headway adherence
- Threshold headway adherence
- Headway regularity (even headways)
- Optimization (rolling horizon)
 - Models passenger costs explicitly
 - Trade-off between waiting time and in-vehicle time
 - Reduces excessive holding
 - Avoids holding full vehicles
 - Prevents unnecessary reduction of effective capacity
 - Potentially considers operating constraints
 - Excessively late drivers

Rail Operations Control: Decision Factors

- These factors can trigger service control interventions or place constraints on interventions performed for other reasons
- Conflicts between objectives are frequent
- Service control can cause unreliability!
- How can we best coordinate and integrate these objectives and constraints?

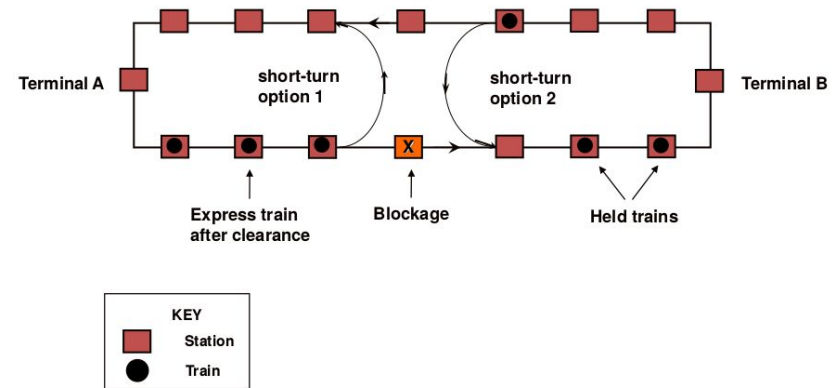

"Diagnosis and Assessment of Operations Control Interventions: Framework and Applications to a High Frequency Metro Line." MST Thesis, André Carrel; MIT, 2009.

MIT Three Levels of Control Problems

- **Routine disturbances** few minutes deviation from schedule
 - speed adjustment
 - dwell time adjustment (selective holding)
 - terminal recovery
- **Short-term disruptions** 5-30 minute blockages
 - holding
 - short-turning
 - expressing
- **Longer-term disruptions** >30 minute blockages
 - single-track reverse direction operations
 - replacement bus service around blockage

MIT Disruption Response Strategies

MIT State of Practice in Operations Control

- Advances in train control systems help minimize impacts of small incidents
- Major disruptions still handled in individual manner based on judgment and experience
- Little effective decision support for controllers
- Simplistic view of objectives and constraints in model formulation
- Substantial opportunities for more effective models

MIT MBTA Green Line Headway Dispatching

Current Operations

- Trains dispatched by on-site inspectors following the schedule

Headway Dispatching Pilot

- Decision support tool delivered on touchscreen tablet
- Even headway dispatching, with constraints
- Contains vehicle and driver information
