

Beyond Verification

Software Synthesis

What do we mean by synthesis

We want to get code from high-level specs

- Python and VB are pretty high level, why is that not synthesis?

Support compositional and incremental specs

- Python and VB don't have this property
 - If I don't like the way the python compiler/runtime is implementing my program, I am out of luck.
- Logical specifications do
 - I can always add additional properties that my system can satisfy
- Specs are not only functional
 - Structural specifications play a big role in synthesis
 - How is my algorithm going to look like.

The fundamental challenge

The fundamental challenge of synthesis is dealing with an uncooperative environment

- For reactive systems, people model this as a game
 - For every move of the adversary (ever action of the environment), the synthesized program must make a counter-move that keeps the system working correctly.
 - The game can be modeled with an automata

The fundamental challenge

The fundamental challenge of synthesis is dealing with an uncooperative environment

- If we are synthesizing functions, the environment provides the inputs
 - i.e. whatever we synthesize must work correctly for all inputs
- This is modeled with a doubly quantified constraint
 - E.g. if the spec is given as pre and post conditions, we have

$$\exists P \forall \sigma (\sigma \models \{pre\}) \Rightarrow (\sigma \models WP(P, \{post\}))$$

- What does it mean to quantify over the space of programs?

Quantifying over programs

Synthesis in the functional setting can be seen as curve fitting

- i.e. we want to find a curve that satisfies some properties

It's very hard to do curve fitting when you have to consider arbitrary curves

- Instead, people use *parameterized* families of curves
- This means you quantify over parameters instead of over functions

This is the first fundamental idea in software synthesis

- People call these Sketches, scaffolds, templates, ...
- They are all the same thing

The Sketch Language

Define parameterized programs explicitly

- Think of the parameterized programs as “programs with holes”

Example: Hello World of Sketching

spec:

```
int foo (int x)
{
    return x + x;
}
```

sketch:

```
int bar (int x) implements foo
{
    return x * ??;
}
```

Integer Hole

Integer Holes \rightarrow Sets of Expressions

Expressions with **??** == sets of expressions

- linear expressions
- polynomials
- sets of variables

$$x^{*??} + y^{*??}$$

$$x^{*x^{*??}} + x^{*??} + ??$$

$$?? \ ? \ x : y$$

Integer Holes → Sets of Expressions

Example: Least Significant Zero Bit

- 0010 0101 → 0000 0010

```
int W = 32;
bit[W] isolate0 (bit[W] x) {      // W: word size
    bit[W] ret = 0;
    for (int i = 0; i < W; i++)
        if (!x[i]) { ret[i] = 1; return ret; }
}
```

Trick:

- Adding 1 to a string of ones turns the next zero to a 1
- i.e. 000111 + 1 = 001000

!(x + ??) & (x + ??)

→

!(x + 1) & (x + 0)

!(x + 1) & (x + 0xFFFF)

!(x + 0) & (x + 1)

!(x + 0xFFFF) & (x + 1)

Integer Holes → Sets of Expressions

Example: Least Significant Zero Bit

- 0010 0101 → 0000 0010

```
int W = 32;
bit[W] isolate0 (bit[W] x) {          // W: word size
    bit[W] ret = 0;
    for (int i = 0; i < W; i++)
        if (!x[i]) { ret[i] = 1; return ret; }
}

bit[W] isolateSk (bit[W] x) implements isolate0 {
    return !(x + ??) & (x + ??) ;
}
```

Integer Holes \rightarrow Sets of Expressions

Expressions with $??$ == sets of expressions

- linear expressions
- polynomials
- sets of variables

$$x^{*??} + y^{*??}$$

$$x^{*}x^{*??} + x^{*??} + ??$$

$$?? \ ? \ x : y$$

Semantically powerful but syntactically clunky

- Regular Expressions are a more convenient way of defining sets

Regular Expression Generators

{| RegExp |}

RegExp supports choice ‘|’ and optional ‘?’

- can be used arbitrarily within an expression

- to select operands {| (x | y | z) + 1 |}
- to select operators {| x (+ | -) y |}
- to select fields {| n(.prev | .next)? |}
- to select arguments {| foo(x | y, z) |}

Set must respect the type system

- all expressions in the set must type-check
- all must be of the same type

Least Significant One revisited

How did I know the solution would take the form

$!(x + ??) \& (x + ??)$.

What if all you know is that the solution involves x , $+$, $\&$ and $!$.

```
bit[W] tmp=0;
{| x | tmp |} = {| (!)?((x | tmp) (& | +) (x | tmp | ??)) |};
{| x | tmp |} = {| (!)?((x | tmp) (& | +) (x | tmp | ??)) |};
return tmp;
```

This is now a set of statements
(and a really big one too)

Sets of statements

Statements with holes = sets of statements

Higher level constructs for Statements too

- repeat

```
bit[W] tmp=0;
repeat(3){
    { | x | tmp | } = { | (!)?((x | tmp) (& | +) (x | tmp | ??)) | };
}
return tmp;
```

repeat

Avoid copying and pasting

- `repeat(n){ s }` \rightarrow $\underbrace{s; s; \dots s;}_n$

- each of the n copies may resolve to a distinct stmt
- n can be a hole too.

```
bit[W] tmp=0;
repeat(??){
    { | x | tmp | } = { | (!)?((x | tmp) (& | +) (x | tmp | ??)) | };
}
return tmp;
```

Keep in mind:

- the synthesizer won't try to minimize n

Solving for a parameterized program

At a high level, two fundamental approaches:

- Search and Test
- Derive in one shot
 - Usually by means of abstraction.

The CEGIS approach

Synthesis reduces to constraint satisfaction

$$\exists \phi. \forall x. Q(x, \phi)$$

Constraints are too hard for standard techniques

- Universal quantification over inputs
- Too many inputs
- Too many constraints
- Too many holes

Insight

Sketches are not arbitrary constraint systems

- They express the high level structure of a program

A small number of inputs can be enough

- focus on corner cases

$$\exists \phi. \forall x \text{ in } E. Q(x, \phi)$$

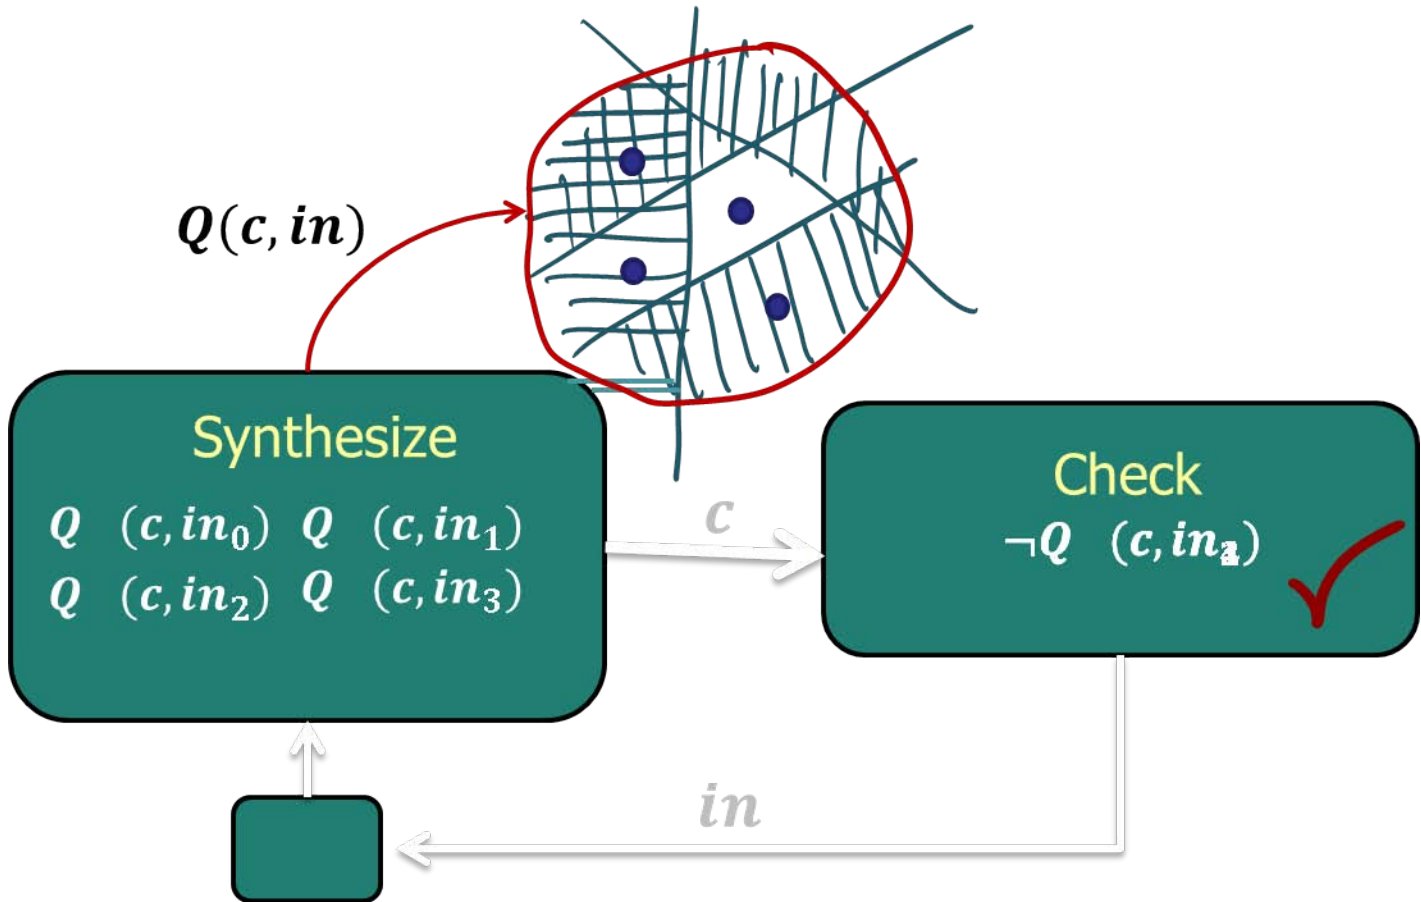

where $E = \{x_1, x_2, \dots, x_k\}$

This is an inductive synthesis problem !

CEGIS Synthesis algorithm

CEGIS

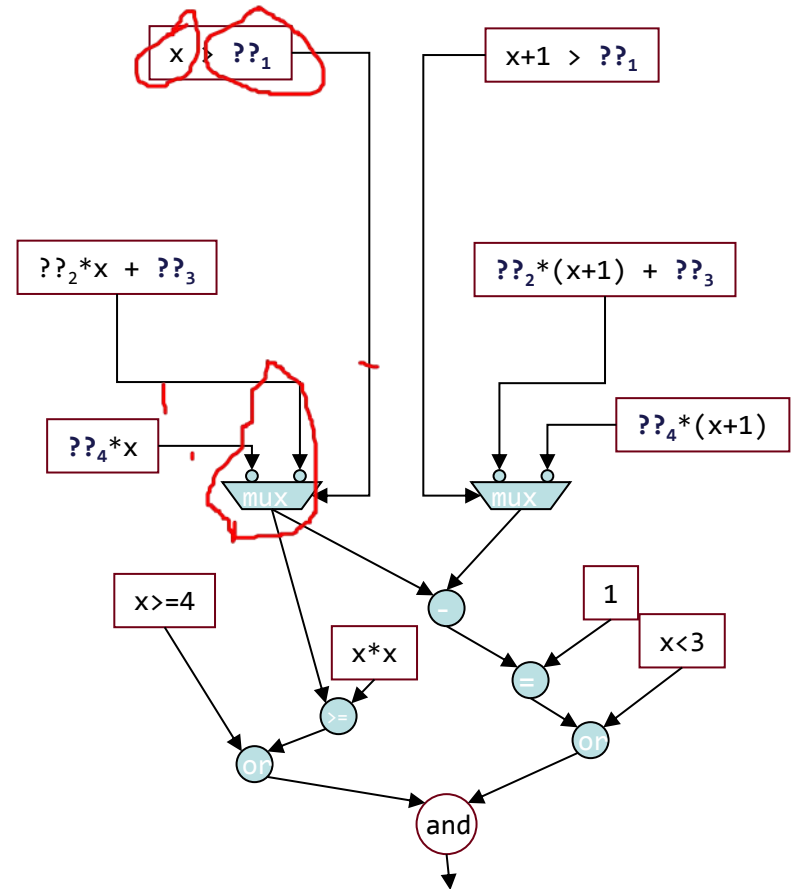

A sketch as a constraint system

```
int lin(int x){
  if(x > ??1)
    return ??2*x + ??3;
  else
    return ??4*x;
}

void main(int x){
  int t1 = lin(x);
  int t2 = lin(x+1);

  if(x<4) assert t1 >= x*x;

  if(x>=3) assert t2-t1 == 1;
}
```

Ex : Population count. 0010 0110 → 3

```
int pop (bit[W] x)
{
  int count = 0;
  for (int i = 0; i < W; i++) {
    if (x[i]) count++;
  }
  return count;
}
```

`int popSketched (bit[W] x)`

`implements pop {`

`repeat(??) {`

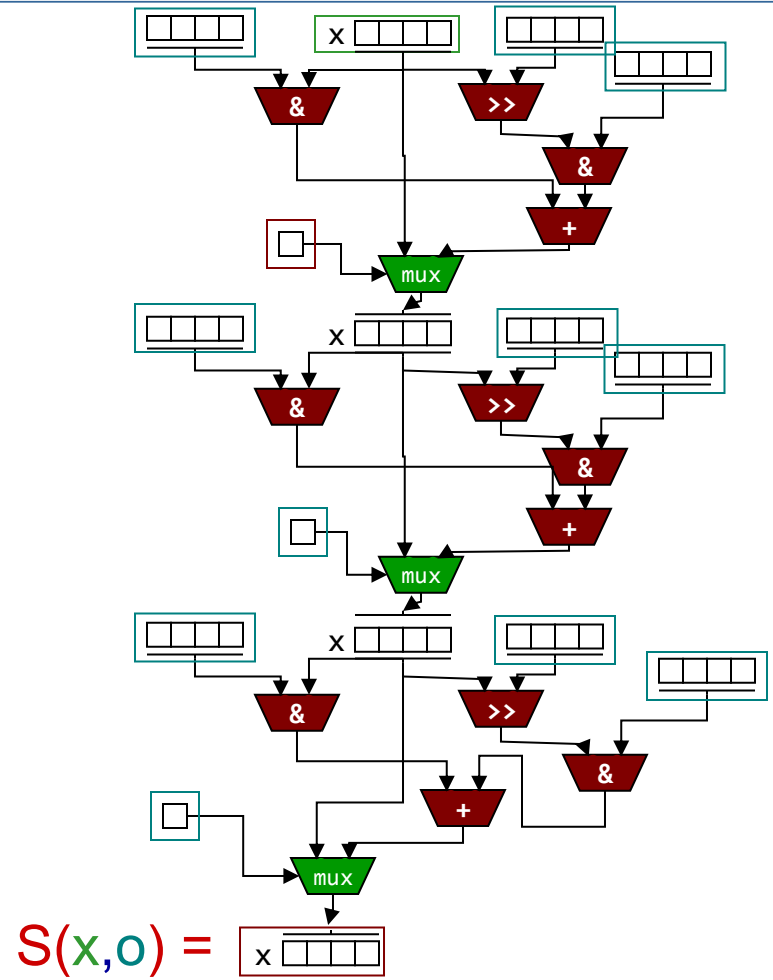

`⇒ x = (x & ??)`

`⇒ + ((x >> ??) & ??);`

`⇒ }`

`⇒ return x;`

`}`
