

## Session #4: Homework Problems

### Problem #1

A photon with a wavelength ( $\lambda$ ) of  $3.091 \times 10^{-7}$  m strikes an atom of hydrogen. Determine the velocity of an electron ejected from the excited state,  $n = 3$ .

### Problem #2

Determine the minimum potential that must be applied to an  $\alpha$ -particle so that on interaction with a hydrogen atom, a ground state electron will be excited to  $n = 6$ .

### Problem #3

Determine if an electron travelling at a velocity of  $7.2 \times 10^6$  km/hr is capable of ionizing a hydrogen atom with its orbiting electron in the ground state.

### Problem #4

Determine for hydrogen the velocity of an electron in an  $n=4$  state.

### Problem #5

Determine the wavelength of radiation emitted by hydrogen atoms upon electron transitions from  $n=6$  to  $n=2$ .

### Problem #6

Calculate the minimum potential (V) which must be applied to a free electron so that it has enough energy to excite, upon impact, the electron in a hydrogen atom from its ground state to a state of  $n=5$ .

### Problem #7

Light of wavelength  $\lambda = 4.28 \times 10^{-7}$  m interacts with a "motionless" hydrogen atom. During this interaction it transfers all its energy to the orbiting electron of the hydrogen. What is the velocity of this electron after interaction?

### Problem #8

What is the *energy gap* (in eV) between the electronic states  $n=3$  and  $n=8$  in a hydrogen atom?

### Problem #9

- (a) From information provided in your Periodic Table of the Elements, determine the *first ionization energies* (in Joules) for the horizontal columns (1) Na to Ar and (2) Ca to Cu.

- (b) On a graph, plot the values obtained as a function of atomic number and attempt to explain the apparent difference in the change of ionization energy with increasing atomic number for the two series of atoms.

**Problem #10**

Determine the energy gap (in eV) between the electronic states  $n=7$  and  $n=8$  in hydrogen.

**Problem #11**

Determine the frequency of radiation capable of generating, in atomic hydrogen, free electrons which have a velocity of  $1.3 \times 10^6 \text{ ms}^{-1}$ .

**Problem #12**

- (a) Determine if an energy level of  $-1.362 \times 10^{-19} \text{ J}$  is an allowed electron energy state in atomic hydrogen.
- (b) If your answer is yes, determine its principal quantum number ( $n$ ). If your answer is no, determine  $n$  for the "nearest allowed state".
