MIT

- ▶ Let  $X$  be a uniformly distributed random variable on  $[-1, 1]$ .

- ▶ Let  $X$  be a uniformly distributed random variable on  $[-1, 1]$ .
  - ▶ Compute the variance of  $X^2$ .

- ▶ Let  $X$  be a uniformly distributed random variable on  $[-1, 1]$ .
  - ▶ Compute the variance of  $X^2$ .
  - ▶ If  $X_1, \dots, X_n$  are independent copies of  $X$ , what is the probability density function for the smallest of the  $X_i$ ?

$$\begin{aligned}\text{Var}[X^2] &= E[X^4] - (E[X^2])^2 \\ &= \int_{-1}^1 \frac{1}{2}x^4 dx - \left(\int_{-1}^1 \frac{1}{2}x^2 dx\right)^2 = \frac{1}{5} - \frac{1}{9} = \frac{4}{45}.\end{aligned}$$

$$\begin{aligned}\text{Var}[X^2] &= E[X^4] - (E[X^2])^2 \\ &= \int_{-1}^1 \frac{1}{2}x^4 dx - \left(\int_{-1}^1 \frac{1}{2}x^2 dx\right)^2 = \frac{1}{5} - \frac{1}{9} = \frac{4}{45}.\end{aligned}$$

- ▶ Note that for  $x \in [-1, 1]$  we have

$$P\{X > x\} = \int_x^1 \frac{1}{2} dx = \frac{1-x}{2}.$$

If  $x \in [-1, 1]$ , then

$$\begin{aligned}P\{\min\{X_1, \dots, X_n\} > x\} \\ = P\{X_1 > x, X_2 > x, \dots, X_n > x\} = \left(\frac{1-x}{2}\right)^n.\end{aligned}$$

So the density function is

$$-\frac{\partial}{\partial x} \left(\frac{1-x}{2}\right)^n = \frac{n}{2} \left(\frac{1-x}{2}\right)^{n-1}.$$

# Moment generating functions

- ▶ Suppose that  $X_i$  are independent copies of a random variable  $X$ . Let  $M_X(t)$  be the moment generating function for  $X$ . Compute the moment generating function for the average  $\sum_{i=1}^n X_i/n$  in terms of  $M_X(t)$  and  $n$ .

- ▶ Write  $Y = \sum_{i=1}^n X_i/n$ . Then

$$M_Y(t) = E[e^{tY}] = E[e^{t \sum_{i=1}^n X_i/n}] = (M_X(t/n))^n.$$

- ▶ Suppose  $X$  and  $Y$  are independent random variables, each equal to 1 with probability  $1/3$  and equal to 2 with probability  $2/3$ .
  - ▶ Compute the entropy  $H(X)$ .

- ▶ Suppose  $X$  and  $Y$  are independent random variables, each equal to 1 with probability  $1/3$  and equal to 2 with probability  $2/3$ .
  - ▶ Compute the entropy  $H(X)$ .
  - ▶ Compute  $H(X + Y)$ .

- ▶ Suppose  $X$  and  $Y$  are independent random variables, each equal to 1 with probability  $1/3$  and equal to 2 with probability  $2/3$ .
  - ▶ Compute the entropy  $H(X)$ .
  - ▶ Compute  $H(X + Y)$ .
  - ▶ Which is larger,  $H(X + Y)$  or  $H(X, Y)$ ? Would the answer to this question be the same for any discrete random variables  $X$  and  $Y$ ? Explain.

▶  $H(X) = \frac{1}{3}(-\log \frac{1}{3}) + \frac{2}{3}(-\log \frac{2}{3})$ .

- ▶  $H(X) = \frac{1}{3}(-\log \frac{1}{3}) + \frac{2}{3}(-\log \frac{2}{3})$ .
- ▶  $H(X + Y) = \frac{1}{9}(-\log \frac{1}{9}) + \frac{4}{9}(-\log \frac{4}{9}) + \frac{4}{9}(-\log \frac{4}{9})$

- ▶  $H(X) = \frac{1}{3}(-\log \frac{1}{3}) + \frac{2}{3}(-\log \frac{2}{3})$ .
- ▶  $H(X + Y) = \frac{1}{9}(-\log \frac{1}{9}) + \frac{4}{9}(-\log \frac{4}{9}) + \frac{4}{9}(-\log \frac{4}{9})$
- ▶  $H(X, Y)$  is larger, and we have  $H(X, Y) \geq H(X + Y)$  for any  $X$  and  $Y$ . To see why, write  $a(x, y) = P\{X = x, Y = y\}$  and  $b(x, y) = P\{X + Y = x + y\}$ . Then  $a(x, y) \leq b(x, y)$  for any  $x$  and  $y$ , so  
$$H(X, Y) = E[-\log a(x, y)] \geq E[-\log b(x, y)] = H(X + Y).$$
