

### ↻ Last Lecture

- ↻ Pendulums and Kinetic Energy of rotation

### ↻ Today

- ↻ Energy and Momentum of rotation

### ↻ Important Concepts

- ↻ Equations for angular motion are mostly identical to those for linear motion with the names of the variables changed.
- ↻ Kinetic energy of rotation adds a new term to the same energy equation, it does not add a new equation.
- ↻ Momentum of rotation gives an additional equation

## Important Reminders

- ↻ Contact your tutor about session scheduling
- ↻ Mastering Physics due today at 10pm.
- ↻ Pset due this Friday at 11am.

## Torque Checklist

### ↻ Make a careful drawing showing **where** forces act

- ↻ Clearly indicate what axis you are using
- ↻ Clearly indicate whether CW or CCW is positive

### ↻ For each force:

- ↻ If force acts at axis or points to or away from axis,  $\tau=0$
- ↻ Draw (imaginary) line from axis to point force acts. If distance and angle are clear from the geometry  $\tau = Fr \sin(\theta)$
- ↻ Draw (imaginary) line parallel to the force. If distance from axis measured perpendicular to this line (lever arm) is clear, then the torque is the force times this distance

### ↻ Don't forget CW versus CCW, is the torque + or -

## Kinetic Energy with Rotation

### ↻ Adds a new term not a new equation!

- ↻ Rotation around any fixed pivot:  $KE = \frac{1}{2} I_{pivot} \omega^2$

- ↻ Moving and rotating:  $KE = \frac{1}{2} I_{CM} \omega^2 + \frac{1}{2} M_{Tot} v_{CM}^2$

## Everything you need to know for Linear & Rotational Dynamics

- $\Sigma \vec{F} = M\vec{a}$
- $\Sigma \vec{\tau} = I\vec{\alpha}$ 
  - This is true for **any fixed** axis and for an axis through the center of mass, even if the object moves or accelerates.
- Rolling **without** slipping:  $v = R\omega$   $a = R\alpha$   $f \neq \mu N$ 
  - Friction does NOT do work!
- Rolling **with** slipping:  $v \neq R\omega$   $a \neq R\alpha$   $f = \mu N$ 
  - Friction does work, usually negative.
  - Rarely solvable without using force and torque equations!

## Kinematics Variables

- |                    |                                 |
|--------------------|---------------------------------|
| → Position $x$     | → Angle $\theta$                |
| → Velocity $v$     | → Angular velocity $\omega$     |
| → Acceleration $a$ | → Angular acceleration $\alpha$ |
| → Force $F$        | → Torque $\tau$                 |
| → Mass $M$         | → Moment of Inertia $I$         |
| → Momentum $p$     | → Angular Momentum $\times$     |

$$\omega = \frac{d\theta}{dt} \quad \alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}$$

## Angular Momentum

- Conserved when external torques are zero or when you look over a very short period of time.
  - True for any fixed axis and for the center of mass
- Formula we will use is simple:  $\vec{L} = I\vec{\omega}$ 
  - Vector nature (CW or CCW) is still important
- Point particle:  $\vec{L} = \vec{r} \times \vec{p}$
- Conservation of angular momentum is a separate equation from conservation of linear momentum
- Angular impulse:  $\vec{\tau} = \frac{d\vec{L}}{dt} \quad \Delta\vec{L} = \int \vec{\tau} dt$
