

## Problem Set 5

### 1. Stopping a Bullet

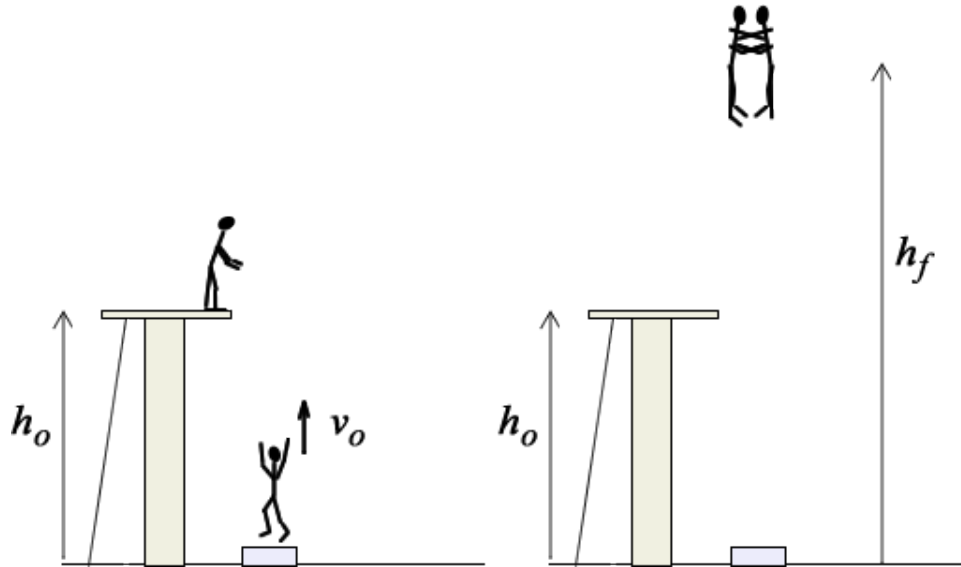

A bullet of mass  $m_1$  traveling horizontally with speed  $u$  hits a block of mass  $m_2$  that is originally at rest and becomes embedded in the block. After the collision, the block slides horizontally a distance  $d$  on a surface with friction, and then falls off the surface at a height  $h$  as shown.

The coefficient of kinetic friction between the block and the surface is  $\mu_k$ . Assume the collision is nearly instantaneous and all distances are large compared to the size of the block. Neglect air resistance.

- What is  $u_{min}$ , the minimum speed of the bullet so that the block falls off the surface? Express your answer in terms of some or all of the following:  $m_1$ ,  $m_2$ ,  $\mu_k$ ,  $d$ ,  $h$  and  $g$  for the gravitational constant.
- Assume that the initial speed of the bullet  $u$  is large enough for the block to fall off the surface. Calculate  $x_f$ , the position where the block hits the ground measured from the bottom edge of the surface. Express your answer in terms of some or all of the following:  $m_1$ ,  $m_2$ ,  $\mu_k$ ,  $u$ ,  $d$ ,  $h$  and  $g$ .

2. **Acrobat and Clown** An acrobat of mass  $m_A$  jumps upwards off a trampoline with an initial speed  $v_0$ . At a height  $h_0$ , the acrobat grabs a clown of mass  $m_B$ . Assume that the time the acrobat takes to grab the clown is negligibly small.

What is the maximum height  $h_f$  reached by the acrobat and clown? Write your answer in terms of some or all of the following:  $m_A$ ,  $m_B$ ,  $g$ ,  $h_0$ , and  $v_0$ .

### 3. Compressive Strength of Bones

The compressive force per area necessary to break the tibia in the lower leg is about  $F/A = 1.6 \times 10^8 \text{ N/m}^2$ . The smallest cross sectional area of the tibia, about  $3.2 \text{ cm}^2$ , is slightly above the ankle. Suppose a person of mass  $m = 60 \text{ kg}$  jumps to the ground from a height  $h_0 = 2.0 \text{ m}$  and absorbs the shock of hitting the ground by bending the knees. Assume that there is constant deceleration during the collision with the ground, and that the person lowers their center of mass by an amount  $d = 1.0 \text{ cm}$  from the time they hit the ground until they stop moving.

- (a) What is the collision time  $\Delta t_{col}$ , to 2 significant figures?
- (b) Find  $N_{ave}$ , the magnitude of the average force exerted by the ground on the person during the collision in Newtons.
- (c) What is the ratio of the average force of the ground on the person to the gravitational force on the person? Can we effectively ignore the gravitational force during the collision?
- (d) Will the person break his ankle?

#### 4. Center of Mass of a Rod

A thin rod has length  $L$  and total mass  $M$  lies along the  $x$  axis.

- (a) Suppose the rod is uniform. Find the position of the center of mass with respect to the left end of the rod in terms of  $L$ ,  $M$ , and  $\hat{i}$ .
- (b) Now suppose the rod is not uniform but has a linear mass density that varies with the distance  $x$  from the left end according to

$$\lambda = \frac{\lambda_0}{L^3} x^3$$

where  $\lambda_0$  is a constant and has SI units of kg/m. The total mass of the rod is still  $M$ . Find  $\lambda_0$  and the position of the center of mass with respect to the left end of the rod. Express your answer in terms of some or all of the following:  $L$ ,  $M$ , and  $\hat{i}$ .

## 5. Two Particles Colliding

Two small particles of mass  $m_1$  and mass  $m_2$  attract each other with a force that varies inversely with the cube of their separation. At time  $t_0$ ,  $m_1$  has a velocity of magnitude  $v_0$ , directed towards  $m_2$ , which is at rest a distance  $d$  away. At time  $t_1$ , the particles collide.

Calculate  $L$ , the distance travelled by particle 1 during the time interval  $t_1 - t_0$ . Express your answer using some or all of the following variables:  $m_1$ ,  $m_2$ ,  $t_0$ ,  $t_1$ ,  $v_0$ , and  $d$ .
